Queueing Models

Characteristics of Queueing Systems

| System           | Customers     | Server(s)               |
|------------------|---------------|-------------------------|
| Reception desk   | People        | Receptionist            |
| Repair facility  | Machines      | Repair person           |
| Garage           | Trucks        | Mechanic                |
| Airport security | Passengers    | Baggage x-ray           |
| Hospital         | Patients      | Nurses                  |
| Warehouse        | Pallets       | Fork-lift Truck         |
| Airport          | Airplanes     | Runway                  |
| Production line  | Cases         | Case-packer             |
| Warehouse        | Orders        | Order-picker            |
| Road network     | Cars          | Traffic light           |
| Grocery          | Shoppers      | Checkout station        |
| Laundry          | Dirty linen   | Washing machines/dryers |
| Job shop         | Jobs          | Machines/workers        |
| Lumberyard       | Trucks        | Overhead crane          |
| Sawmill          | Logs          | Saws                    |
| Computer         | Email         | CPU, disk               |
| Telephone        | Calls         | Exchange                |
| Ticket office    | Football fans | Clerk                   |
| Mass transit     | Riders        | Buses, trains           |

## Examples of Queueing Systems

A candy manufacturer has a production line that consists of three machines separated by inventory in-process buffers. The first machine makes and wraps the individual pieces of candy, the second packs 50 pieces in a box, and the third machine seals and wraps the box. The two inventory buffers have capacities of 1000 boxes each. As illustrated by figure, the system is modeled as having three service centers, each center having  $c = 1$  server (a machine), with queue capacity constraints between machines. It is assumed that a sufficient supply of raw material is always available at the first queue. Because of the queue capacity constraints, machine 1 shuts down whenever its inventory buffer (queue 2) fills to capacity, and machine 2 shuts down whenever its buffer empties.

## Examples of Queueing Systems

Consider a discount warehouse where customers may either serve themselves or wait for one of three clerks, then finally leave after paying a single cashier. The system is represented by the flow diagram in figure. The subsystem, consisting of queue 2 and service center 2. Other variations of service mechanisms include batch service (a server serving several customers simultaneously) and a customer requiring several servers simultaneously. In the discount warehouse, a clerk might pick several small orders at the same time, but it may take two of the clerks to handle one heavy item.

## Queueing Notations

$A/B/c/N/K$

These letters represent the following system characteristics:

- A** represents the interarrival-time distribution.
- B** represents the service-time distribution. Common symbols for A and B include
  - M (exponential or Markov),
  - D (constant or deterministic),
  - Ek (Erlang of order k),
  - PH (phase-type),
  - H (hyperexponential),
  - G (arbitrary or general), and
  - GI (general independent).
- c** represents the number of parallel servers.
- N** represents the system capacity.
- K** represents the size of the calling population

## Queueing Notations

$A/B/c/N/K$

For example,

- $M/M/1/\infty/\infty$  indicates a single-server system that has unlimited queue capacity and an infinite population of potential arrivals. The interarrival times and service times are exponentially distributed.
- When N and K are infinite, they may be dropped from the notation. For example,  $M/M/1/\infty/\infty$  is often shortened to  $M/M/1$ .
- The nurse attending 5 hospital patients might be represented by  $M/M/1/5/5$ .

## Understanding and Evaluating Queueing System Performance over Time

- Average waiting time: This is the average time a customer spends waiting in the queue before being served. It is an important measure of the quality of service provided by the system.
- Average queue length: This is the average number of customers waiting in the queue for service. It is an important measure of the efficiency of the system.
- Utilization: This is the proportion of time that the server is busy serving customers. A high utilization indicates that the system is being used efficiently, while a low utilization indicates that there is excess capacity.
- Throughput: This is the number of customers served by the system per unit of time. It is an important measure of the capacity of the system.
- Blocking probability: This is the probability that a customer is blocked (i.e., denied service) due to the system being at full capacity. It is an important measure of the effectiveness of the system in handling demand.

## Average waiting time

- Primary long-run measures of performance:
  - Long-run time-average number of customers in the system ( $L$ ) and in the queue ( $L_Q$ )
  - Long-run average time spent in system ( $w$ ) and in the queue ( $w_Q$ ) per customer
  - Server utilization, or proportion of time that a server is busy ( $\rho$ )
  - "System" refers to the waiting line plus service mechanism; "queue" refers to waiting line alone
- Other measures of performance:
  - Long-run proportion of customers delayed in queue longer than  $t_0$  time units
  - Long-run proportion of customers turned away due to capacity constraints
  - Long-run proportion of time waiting line contains more than  $k_0$  customers
  - Defines measures of performance for general  $G/G/c/N/K$  queueing system
  - Discusses relationships and estimation using ordinary sample average or time-integrated sample average

## Long-Run Measures of Performance of Queueing Systems

Consider a queueing system over a period of time  $T$ , and let  $L(t)$  denote the number of customers in the system at time  $t$ . A simulation of such a system is shown in Figure .

Figure: Simulation of a queueing system over a period of time  $T$

## Long-Run Measures of Performance of Queueing Systems

Figure: Simulation of a queueing system over a period of time  $T$

Let  $T_i$  denote the total time during  $[0, T]$  in which the system contained exactly  $i$  customers. In Figure 6, it is seen that  $T_0 = 3$ ,  $T_1 = 12$ ,  $T_2 = 4$ , and  $T_3 = 1$ . In general, the time-weighted-average number in a system is defined by:

$$L = \sum_{i=0}^{\infty} i \frac{T_i}{T}$$

Notice that  $T_i/T$  is the proportion of time the system contains exactly  $i$  customers. The estimator  $L$  is an example of a time-weighted average.

## Solution

- Let  $T_i$  denote the total time during  $[0, T]$  in which the system contained exactly  $i$  customers.
- In Figure 6,  $T_0 = 3$ ,  $T_1 = 12$ ,  $T_2 = 4$ , and  $T_3 = 1$ .
- Using Eq. (1), the time-weighted-average number of customers in the system is:

$$\begin{aligned}
 L &= \frac{\sum_{i=0}^{\infty} iT_i}{T} \\
 &= \frac{0(3) + 1(12) + 2(4) + 3(1)}{20} \\
 &= \frac{23}{20} \\
 &= 1.15 \text{ customers.}
 \end{aligned}$$

## Queueing System and Waiting Customers

Suppose that Figure represents a single-server queue—that is, a  $G/G/1/N/K$  queueing system ( $N \geq 3$ ,  $K \geq 3$ ). Then the number of customers waiting in queue is given by  $L_Q(t)$ , defined by

$$L_Q(t) = \begin{cases} 0, & \text{if } L(t) = 0, \\ L(t) - 1, & \text{if } L(t) \geq 1, \end{cases}$$

and shown in Figure .

## Queueing System and Waiting Customers

Suppose that Figure represents a single-server queue—that is, a  $G/G/1/N/K$  queueing system ( $N \geq 3$ ,  $K \geq 3$ ). Then the number of customers waiting in queue is given by  $L_Q(t)$ , defined by

$$L_Q(t) = \begin{cases} 0, & \text{if } L(t) = 0, \\ L(t) - 1, & \text{if } L(t) \geq 1, \end{cases}$$

and shown in Figure .

Thus,  $T_{0,Q} = 5 + 10 = 15$ ,  $T_{1,Q} = 2 + 2 = 4$ , and  $T_{2,Q} = 1$ . Therefore,

$$L_Q = \frac{0(15) + 1(4) + 2(1)}{20} = 0.3 \text{ customers.}$$
